GENERAL INFORMATION

B5SM air handlers are shipped from the factory ready for installation in a horizontal position. The units can be easily reconfigured in the field for vertical applications. The return air opening is interchangeable between the bottom of the unit and the top panel simply by switching the filter-rack with the return air cover panel. For either configuration, sufficient clearance must be provided on the sides of the unit to allow access for servicing the blower, motor, coil assembly, and filters.

This unit has been designed and tested for capacity and efficiency in accordance with A.R.I. Standards. This unit will provide many years of safe and dependable comfort, providing it is properly installed and maintained. With regular maintenance, this unit will operate reliably year after year. Abuse, improper use, and/ or improper maintenance can shorten the life of the appliance and create unsafe hazards.

Before You Install the Air Handler

- \checkmark This equipment is securely packed at the time of shipment and upon arrival should be carefully inspected for damage prior to installing the equipment at the job site. Claims for damage (apparent or concealed) should be filed immediately with the carrier.
- $\sqrt{}$ The cooling load of the area to be conditioned must be calculated and a system of the proper capacity selected.
- $\sqrt{}$ Check the electrical supply and verify the power supply is adequate for unit operation. The system must be wired and provided with circuit protection in accordance with local building codes. If there is any question concerning the power supply, contact the local power company.
- $\sqrt{}$ The air handler should be installed before routing the refrigerant tubing. Refer to the indoor unit's installation instructions for installation details.
- \sqrt{Verify} the air delivery of the/air handler is adequate to handle the static pressure drop of the coil, filter, and duct work.
- $\sqrt{\rm Please}$ consult your dealer for maintenance information and availability of maintenance contracts. Please read all instructions before installing the unit.

Locating the Air Handler

- Survey the job site to determine the best location for mounting the unit.
- Overhead obstructions, poorly ventilated areas, and areas subject to accumulation of debris should be avoided.
- Consideration should be given to availability of electric power, service access, noise, and shade.

Field Connections for Electrical Power Supply

- All wiring must comply with current provisions of the National Electrical Code (ANSI/NFPA 70) and with applicable local codes having jurisdiction.
- The minimum size of electrical conductors and circuit protection must be in compliance with information listed on the outdoor unit data label.
- Electrical power supplied to the unit must be adequate for proper operation of the equipment. The system must be wired and provided with circuit protection in accordance with local building codes.

Air Ducts

This unit is designed only for use with a supply and return duct. Air ducts should be installed in accordance with the standards of the National Fire Protection Association Standard for Installation of Air Conditioning Systems (NFPA 90A), Standard for Installation of Residence Type Warm Air Heating and Air Conditioning Systems (NFPA 90B), and all applicable local codes. NFPA publications are avaialable by writing to: National Fire Protection Association, Batterymarch Park, Quincy, ME 02269 or visit www.NFPA.org on the web.

- Design the duct work according to methods described by the Air Conditioning Contractors of America (ACCA).
- The return air duct must have the same free area as the opening provided on the blower coil unit.
- Duct work should be attached directly to the unit flanges for horizontal and vertical applications. See Figures 4 or 5 (pages 10 or 11).

Unconditioned Spaces

All duct work passing through unconditioned space must be properly insulated to minimize duct losses and prevent condensation. Use insulation with an outer vapor barrier. Refer to local codes for insulation material requirements.

Acoustical Duct Work

Certain installations may require the use of acoustical lining inside the supply duct work.

- Acoustical insulation must be in accordance with the current revision of the Sheet Metal and Air Conditioning Contractors National Association (SMACNA) application standard for duct liners.
- Duct lining must be UL classified batts or blankets with a fire hazard classification of FHC-25/50 or less.
- Fiber duct work may be used in place of internal duct liners if the fiber duct work is in accordance with the current revision of the SMACNA construction standard on fibrous glass ducts. Fibrous duct work and internal acoustical lining must be NFPA Class 1 air ducts when tested per UL Standard 181 for Class 1 ducts.

AIR HANDLER INSTALLATION

Connecting Refrigerant Tubing

Packaging Removal

Remove the shipping crate and User's Manual from the equipment. Take care not to damage the tubing connections when removing the crate.

Minimum Clearance Requirements

This air handler must be installed with ample clearance for easy access to the air filters, blower assembly, and, controls. Allow 24 inches minimum clearance from the front of the motor and refrigerant access panels for service and maintenance. However 36 inches is strongly recommended.

Horizontal Mounting Applications

B5SM air handlers can be suspended from support rods at each corner and are supplied with the required 1/2-13 NC hardware. The installer only needs to supply the $\frac{1}{2}$ " full threaded support rods in an appropriate length for their application. **NOTE:** These units can be supported with 3/8" full threaded support rods, however all mounting hardware must be field supplied. Once in position, verify the unit is level. See Figure 4 (page 10).

A CAUTION:

When raising the air-handler for horizontal mounting, always use safe lifting methods and equipment. Always support the unit along its entire width. Failure to do so may result in damage to the lower panels or other equipment. If determined safe for your application the shipping pallet may be utilized with a forklift for this operation.

Vertical Mounting Applications

Verify the unit is level and there is adequate clearances to service the unit and provide the minimum 2" trap needed for the condensate drain. See Figure 5 (page 11).

Condensate Drain

B5SM air handlers have condensate drain ports on both sides of the unit, and may be configured for drainage from the left, right or both sides (Figures 4 or 5). Connection to the drains can be made with a 3/4" threaded PVC adapter.

Units are configured at the factory with the service side drain open and a threaded PVC drain plug installed on the opposite side. Each drain line installed requires its own drain trap. To ensure proper drainage, the installed drain trap(s) must provide a minimum trap of 2 inches. **Note:** It is recommended that a secondary drain pan be used when the unit is hung above an enclosed ceiling. WARNING:

Evaporator Coils are factory shipped with a nitrogen charge. Avoid direct face exposure or contact with valve when gas is escaping. Always ensure adequate ventilation is present during the depressurization process. Any uncertainties should be addressed before proceeding.

- When connecting refrigerant linesets together, it is recommended that dry nitrogen be flowing through the joints during brazing. This will prevent internal oxidation and scaling from occurring.
- Refrigerant tubing should be routed in a manner that minimizes the length of tubing and the number of bends in the tubing.
- Refrigerant tubing should be supported in a manner that the tubing will not vibrate or abrade during system operation.
- Tubing should be kept clean of foreign debris during installation.
- Every effort should be made by the installer to ensure that the field installed refrigerant containing components of the system have been installed in accordance with these instructions and sound installation practices to insure reliable system operation and longevity.
- Always refer to the installation instructions supplied with the outdoor unit for piping requirements. The suction and liquid lines must be sized in accordance with the condensing unit specifications.
- If precise forming of refrigerant lines is required, a copper tubing bender is recommended. Avoid sharp bends and contact of the refrigerant lines with metal surfaces.
- A filter dryer is provided with the unit and must be installed in the liquid line of the system. If the installation replaces a system with a filter dryer already present in the liquid line, the filter dryer must be replaced with the one supplied with the unit. The filter dryer must be installed in strict accordance with the manufacturer's installation instructions.
- B5SM air handlers are supplied with a direct expansion refrigerant coil and thermostatic expansion valves. Refrigerant line connections are located on the motor side (service side) of cabinet and require sweat connections.

- The B5SM-120 air handler has a dual circuit coil and the B5SM-090 has a single circuit coil.
- The B5SM-120 air handler is charged through service valves on the end of the liquid tube for each circuit. These must be removed before brazing the line sets. The B5SM-090 is charged through a service valve inside the unit, which should not be removed.
- Before brazing the B5SM-090, remove the core from the service port. Failure to do this may result in a leak at the service valve. Replace the core and cap once brazing is complete.
- Optional equipment such as liquid line solenoid valves, low ambient, etc., should be installed in strict accordance with the manufacturer's installation instructions.

Filter Requirements

B5SM air handlers are shipped with three permanent 1" filters; however the filter rack can be converted to accommodate a 2" filter. To convert to a 2" filter:

- 1. Remove all filters from the unit.
- 2. Locate and remove the 4 screws (Figure 1) holding the bottom filter slide assembly (latch end) to the filter rack frame. **NOTE:** Be careful when removing the slide assembly so it does not drop into unit and cause damage to the coil.
- 3. Remove the 4 screws securing the "L" bracket to the "Z" bracket.
- 4. Rotate the "L" bracket 180 degrees, and reposition it so it mounts flush with the "Z" bracket. See Figure 1.
- 5. Secure the filter slide assembly together with the four screws.

6. Re-install the filter slide assembly back into the filter rack frame and secure with the 4 screws removed earlier. If replacing factory supplied filters with disposable filters, use only 2" disposable filters.

Accessing the filters does not require tools and can be performed from either side of the filter-rack. On the service side of the unit, locate the release knob at the base of the filter rack and rotate clockwise to unlock, then pull up and out to remove the filter access panel. On the blower side, use the same method but rotate counter-clockwise to unlock.

ELECTRICAL WIRING

🖄 WARNING:

To avoid risk of electrical shock, personal injury, or death, disconnect all electrical power to the unit before performing any maintenance or service. The unit may have more than one electrical supply.

Label all wires prior to disconnection when servicing the unit. Wiring errors can cause improper and dangerous operation.

- Electrical connections must be in compliance with all applicable local codes and ordinances, and with the current revision of the National Electric Code (ANSI/NFPA 70).
- For Canadian installations, the electrical connections and grounding shall comply with the current Canadian Electrical Code (CSA C22.1 and/or local codes).

Pre-Electrical Checklist:

- $\sqrt{}$ Verify that the voltage, frequency, and phase of the supply source match the specifications on the unit rating plate. The label is located near the refrigerant lines.
- \sqrt{Verify} that the service provided by the utility is sufficient to handle the additional load imposed by this equipment.
- √ Phase balance on 3 phase units must always be checked. See Unbalanced 3-Phase Supply Voltage (page 8).

Line Voltage

- It is recommended that the line voltage to the unit be supplied from a dedicated branch circuit containing the correct fuse or circuit breaker for the unit.
- An electrical disconnect must be located within sight of and readily accessible to the unit. This switch shall be capable of electrically de-energizing the outdoor unit. See unit data label for proper incoming field wiring. Any other wiring methods must be acceptable to authority having jurisdiction.
- Refer to the unit wiring label for proper high and low voltage wiring.
- Use only copper wire for the line voltage power supply to this unit (Table 2, page 6). Use proper code agency listed conduit and a conduit connector for connecting the supply wires to the unit.
- Overcurrent protection must be provided at the branch circuit distribution panel and sized as shown on the unit rating label and according to applicable local codes. See the unit rating plate for maximum circuit ampacity and maximum overcurrent protection limits.
- If replacing any of the original wires supplied with the unit, the replacement wire must be copper wire consisting of the same gauge and temperature rating.
- Provide power supply for the unit in accordance with the unit wiring diagram, and the unit rating plate. The installer should become familiar with the wiring diagram/

schematic before making any electrical connections to the unit. See Figure 6 (page 13).

- These air handlers can be purchased in both single and three phase power configurations, all single phase equipment is shipped from the factory ready for field connections. For electrical connection locations see Figures 4 or 5 (pages 10 or 11).
- Three phase units are shipped from the factory preconfigured for high voltage operation. The 460 volt, 60 hertz units may be reconfigured in the field for the other voltages indicated on the unit rating label . For additional Maximum Current Ampacity (MCA), or Maximum Overcurrent Protection (MOP) information, refer to the unit rating label. For proper high voltage wiring or other wiring requirements refer to the Wiring Diagram (Figure 6).
- Internally mounted circuit breakers are available as field installed options. These circuit breakers can be used as an electrical disconnect.

Thermostat Connections

- Thermostat connections shall be in accordance with the instructions supplied with the thermostat and the indoor equipment. The low voltage wires must be properly connected to the units low voltage terminal block.
- A single stage thermostat is used with this equipment and must operate in conjunction with any installed accessories. A typical AC and air handler hookup is shown in Figure 7 (page 14). For heat pump and air handler connections, see Figure 8 (page 15).
- The thermostat should be mounted about 5 feet above the floor on an inside wall. DO NOT install the thermostat on an outside wall or any other location where its operation may be adversely affected by radiant heat from fireplaces, sunlight, or lighting fixtures, and convective heat from warm air registers or electrical appliances. Refer to the thermostat manufacturer's instruction sheet for detailed mounting and installation information.

Electrical Wiring with a Duct Heater

Slip-in duct heaters are available as an accessory with the B5SM air handler. See Table 3 for available sizes. These heaters mount in the supply duct external to the air handler. The heater kits are available in 10, 16, 26, and 36 KW sizes and 240 or 460 voltages. All heater kits are set up for three phase operation. To wire the heater kits to the B5SM air handler unit, refer to the Installation Instructions supplied witht he kit.

Unbalanced 3-Phase Supply Voltage

Voltage unbalance occurs when the voltages of all phases of a 3-phase power supply are no longer equal. This unbalance reduces motor efficiency and performance. Some underlying causes of voltage unbalance may include: Lack of symmetry in transmission lines, large single-phase loads, and unbalanced or overloaded transformers. A motor should never be operated when a phase imbalance in supply is greater than 2%.

Perform the following steps to determine the percentage of voltage imbalance:

1. Measure the line voltages of your 3-phase power supply where it enters the building and at a location that will only be dedicated to the unit installation. (at the units circuit protection or disconnect).

2. Determine the average voltage in the power supply.

In this example, the measured line voltages were 451, 460, and 453. The average would be 454 volts (451 + 460 + 453 = 1,364 / 3 = 454).

3. Determine the maximum deviation:

4. Determine percent of voltage imbalance by using the results from steps 2 & 3 in the following equation.

% Voltage Imbalance = 100 x ·

max voltage deviation from average voltage

average voltage

The amount of phase imbalance (1.32%) is satisfactory since the amount is lower than the maximum allowable 2%. Please contact your local electric utility company if your voltage imbalance is more than 2%.

Grounding

🖄 WARNING:

The unit cabinet must have an uninterrupted or unbroken electrical ground to minimize personal injury if an electrical fault should occur. Do not use gas piping as an electrical ground!

This unit must be electrically grounded in accordance with local codes or, in the absence of local codes, with the National Electrical Code (ANSI/NFPA 70) or the CSA C22.1 Electrical Code. Use the grounding lug provided in the control box for grounding the unit.

STARTUP AND ADJUSTMENTS

Pre-Start Check List

Prior to start-up, complete the following inspection:

- \sqrt{Verify} the unit is level and condensate can drain. Check condensate drain line(s) for proper slope and trap.
- \sqrt{Verify} the air handler is mounted securely.
- $\sqrt{\rm Verify}$ the surrounding area and top of the unit is free from obstructions and debris.
- $\sqrt{\rm Check}$ all ductwork connections. Make sure the duct work is adequetly sealed to prevent air leakage.
- $\sqrt{}$ Check all coil connections for leaks.
- \sqrt{Verify} that the line voltage power leads are securely connected and the unit is properly grounded.
- $\sqrt{}$ Verify that the low voltage wires are securely connected to the correct leads on the low voltage terminal strip. Make sure the thermostat is wired correctly.
- $\sqrt{}$ Verify the blower rotates properly. Check the blower belt between the pulleys for proper tension and alignment.
- $\sqrt{\rm Verify}$ the power supply branch circuit overcurrent protection is sized properly.
- $\sqrt{\rm Verify}$ all filters are in place and all equipment access/ control panels are in place

Motor Sheave Adjustment

The motor sheave consists of an outer, moveable pulley face and an inner stationary face. To adjust the motor sheave,

- 1. Relieve the belt pressure by loosening motor mount bolts and the belt tensioning bolts on the motor mount.
- 2. Move the blower fan belt out of the way (if necessary) and loosen the set screw in the outer sheave face.
- 3. Rotate the face in increments of one half or full turns only. **NOTE:** This maintains the set screw position precisely over the flats on the pulley hub. Rotating the sheave clockwise (when viewed from the lead end of motor - opposit end of shaft) will make the blower run slower which decreases airflow. Rotating the sheave counter clockwise (as viewed from lead end) will cause the blower to speed up.
- 4. Tighten the setscrews after the desired adjustment has been made and verify the moveable face is properly secured.

Pulley Alignment

Inspect the pulley alignment between the motor sheave and blower pulley. If a misalignment occurs, adjust the location of the motor sheave by loosening the set-screw in the stationary face of the motor sheave. Relocate the sheave assembly on the motor shaft to ensure the belt will be straight and aligned (Figure 2). Tighten the set-screw and then reinstall the fan belt. Tighten the tensioning bolts as described below.

Belt Tensioning

Proper belt tension can be determined by testing the belt deflection at the midpoint of the pulleys. The belt should deflect ¼" per foot of span between the centers of the pulleys (Figure 3). After the proper tension has been applied, tighten the motor mount bolts to secure the assembly, and visually inspect the area to ensure all tools have been removed. Inspect all wire harness and routings in the vicinity and make sure there is adequate clearance for the wire harness.

Blower Adjustments - 3 phase units only

If blower is turning opposite of arrow direction, disconnect all power to unit and allow all rotating equipment to stop, then interchange any two field wired leads at the terminal block OR disconnect connections.

The blower speed has been preset at the factory. For optimum system performance and comfort, it may be

Figure 2. Proper Belt Alignment

Figure 3. Proper Belt Tension

necessary to change the factory set speed. Adjustment of the blower speed is made through varying the pitch of the motor pulley, this adjustment allows for a wide range of installation applications. Refer to Table 4 (page 12) for blower performance data.

<u> WARNING:</u>

Never perform maintenance on energized or rotating equipment. Always disconnect electrical power and allow all rotating equipment to stop before servicing the unit. Failure to do so may result in personal injury, loss of limb, or death from electrical shock or entanglement in moving parts.

UNIT MAINTENANCE

The maintenance information listed below should be performed in accordance with the Maintenance Schedule shown in Figure 9 (page 16).

Filters

To clean permanent filters, remove the filters and wash gently with mild soap and water. Rinse in clean, hot water and allow to drain & dry thoroughly before reinstalling.

Drain Pan

The drain pan and the drain lines should be cleaned to allow condensate to drain properly. Remove any accumulation of residue or sludge from the drain pan. Inspect in and around the drain pan for rust, holes, and leaks.

V-Belts

Inspect for cracks, tears, and excessive or abnormal wear. V-belts tend to elongate over time with normal application and use. Ensure the belt always maintains adequate tension without over tightening. Belts which have been over tightened will wear out rapidly and may cause motor and blower bearings to receive undue strain and wear. As a result the unit could experience excessive vibration and noise problems.

Blower Bearings

The blower assembly incorporates sealed bearings. Under normal operating conditions, no maintenance is necessary for the life of the equipment.

Blower Fan Wheel

Inspect the blower wheel blades for accumulations of dirt and clean if necessary. Inspect mounting nut for tightness when done.

Blower Motor and Assembly

Inspect the blower assembly and motor mounting brackets for tightness and corrosion. Correct deficiencies if neccessary. The blower motor contains sealed bearings and under normal operating conditions, no maintenance is necessary for the life of the equipment.
